Pollen season is getting longer and more intense with climate change
16 March 2022, by Yingxiao Zhang and Allison L. Steiner

The maps on the left show the recent average pollen season length in days for three types of plants: platanus, or plane trees, such as sycamores; betula, or birch; and ambrosia, or ragweed. The maps on the right show the expected changes in total days by the end of the century if carbon dioxide emissions continue at a high rate. Credit: Zhang and Steiner, 2022

Brace yourselves, allergy suffers—new research shows pollen season is going to get a lot longer and more intense with climate change.

Our latest study finds that the U.S. will face up to a 200% increase in total pollen this century if the world continues producing carbon dioxide emissions from vehicles, power plants and other sources at a high rate. Pollen season in general will start up to 40 days earlier in the spring and last up to 19 days longer than today under that scenario.

As atmospheric scientists, we study how the atmosphere and climate affect trees and plants. While most studies focus on pollen overall, we zoomed in on more than a dozen different types of grasses and trees and how their pollen will affect regions across the U.S. in different ways. For example, species like oak and cypress will give the Northeast the biggest increase, but allergens will be on the rise just about everywhere, with consequences for human health and the economy.

If your head is pounding at just the thought of it, we also have some good news, at least for knowing in advance when pollen waves are coming. We're working on using the model from this study to develop more accurate local pollen forecasts.

Why pollen is increasing

Let's start with the basics. Pollen—the dust-like grains produced by grasses and plants—contains the male genetic material for a plant's reproduction.

of the future pollen increase will be rising carbon dioxide emissions.

The higher temperature will extend the growing season, giving plants more time to emit pollen and reproduce. Carbon dioxide, meanwhile, fuels photosynthesis, so plants may grow larger and produce more pollen. We found that carbon dioxide levels may have a much larger impact on pollen increases than temperature in the future.

**Pollen changes will vary by region**

We looked at 15 different pollen types, rather than treating all pollen the same as many past studies have.

Typically, pollination starts with leafy deciduous trees in late winter and spring. Alder, birch and oak are the three top deciduous trees for causing allergies, though there are others, like mulberry. Then grasses come out in the summer, followed by ragweed in late summer. In the Southeast, evergreen trees like mountain cedar and juniper (in the cypress family) start in January. In Texas, "cedar fever" is the equivalent of hay fever.

We found that in the Northeast, pollen seasons for a lot of allergenic trees will increasingly overlap as temperatures and carbon dioxide emissions rise. For example, it used to be that oak trees would release pollen first, and then birch would pollinate. Now we see more overlap of their pollen seasons.

In general, pollen season will change more in the north than in the south, because of larger temperature increases in northern areas.

Southeastern regions, including Florida, Georgia and South Carolina, can expect large grass and weed pollen increases in the future. The Pacific Northwest is likely to see peak pollen season a month earlier because of the early pollen season of alder.

Silver lining: We can improve pollen forecasting **Pollen levels are already on the rise**

Most pollen forecasts right now provide a very broad estimate. Part of the problem is that there aren't many observing stations for pollen counts. A study in 2021 found that the overall pollen season was already about 20 days longer in North America than it was in 1990 and pollen...
concentrations were up about 21%.

Increasing pollen levels in the future will have a much broader impact than a few sniffles and headaches. Seasonal allergies affect about 30% of the population, and they have economic impacts, from health costs to missed working days.
